The West Sahara-Sahel of Africa, can be considered one of the most heterogeneous and diverse arid areas in the world, covering up to twelve ecoregions (Olson *et al.* 2001). However, due to its remoteness and political instability/conflicts during the last decades, biodiversity distribution knowledge in West Sahara-Sahel (WSS) is scarce in comparison with other regions (Brito *et al.* 2014, Durant *et al.* 2014). Despite 105 mammals having been recorded in West Sahara-Sahel (IUCN 2015), detailed knowledge on their distribution and ecology is known for just a handful of species (Vale *et al.* 2016). Within mammals, felids are among the most challenging to study and least known, due to their secretive behaviour and generally highly threatened status in the area (Belbachir *et al.* 2015). In such a scenario, it is important to improve the understanding of their distribution in order to develop effective conservation and management strategies (Dorcas & Wilson 2009).

The sandcat (*Felis margarita* Loche, 1858) is the only cat to occur exclusively in deserts. Throughout its range it inhabits vegetated sand desert, sand dune plains, sand and gravel desert, but also rocky desert habitats in some parts of its range, questioning its need for sandy areas (Schauenberg 1974, Hemmer *et al.* 1976, Cole & Wilson 2015). Soil stability seems to be important for prey availability (small-mammal prey often live clustered around vegetation

and generally do not venture onto bare sand) and for stable den establishment. In spite of this, this species is more common in sandy deserts and less common where the substrate is compacted or composed of clay (Cole & Wilson 2015). The African wildcat (*Felis lybica* Forster, 1780) in comparison is a generalist species with a broad habitat tolerance. It is found from deserts, scrubland, and savannahs to grasslands and mountain forests. Its distribution in WSS is mainly restricted to coastal and mountain areas (Vale *et al.* 2016).

Based on a combination of literature published records, scientific collection specimens, biodiversity citizen science resources (Observation.org) and data from recent field campaigns (Appendices 1 and 2), we provide an updated distribution map of these species in the WSS, particularly, in the lower Draa region of SW Morocco (Fig. 1). The field campaign records are opportunistic observations of animals found in water cisterns over a survey period from 2012-2018. These cisterns are subterranean, usually concrete structures with small, surface-level entrances where rainwater is drained into. Although some are reliably filled with water, many are dry for long periods of time. Animals falling in are at risk of either being trapped or drowning.

These new records highlight a broader extent of occurrence of *Felis margarita* than previously thought. The IUCN Red List distribution

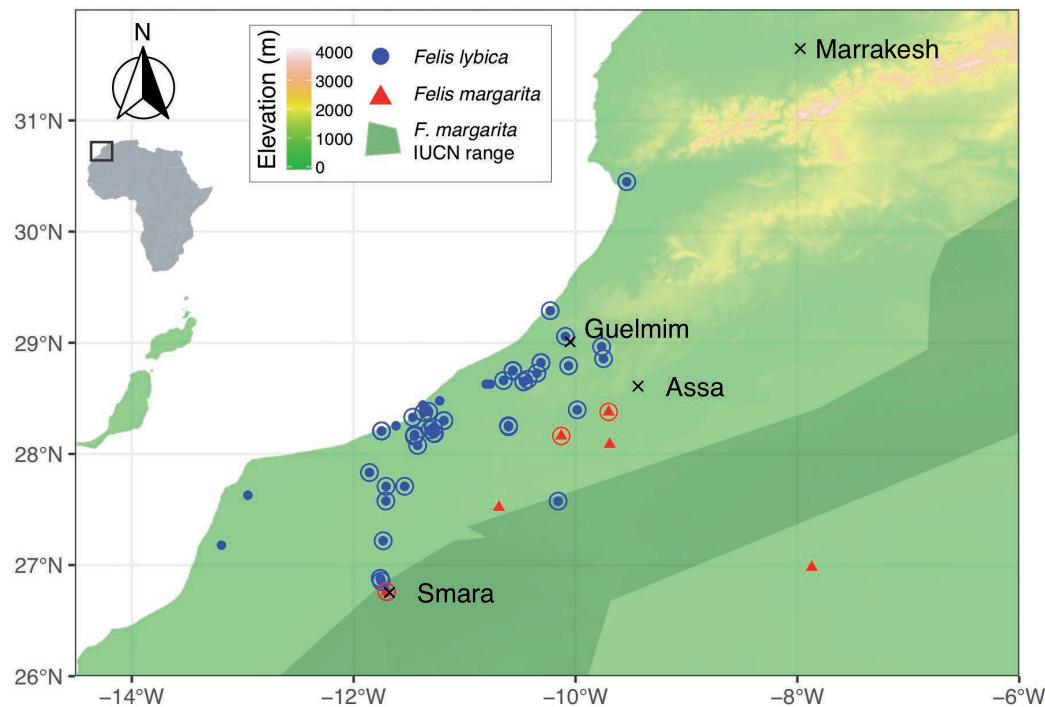

Figure 1. Topological map of the Lower Draa region in West Sahara-Sahel showing records of *Felis margarita* (red triangles) and *F. lybica* (blue points). New records published here are annotated with a circle around the dot. The IUCN range map of *F. margarita* is also shown as a translucent polygon. The range of *F. lybica* is not shown as it extends across the entire map.

map (IUCN 2020) for this species seems to underestimate its distribution especially towards the north-western part of its range in the Lower Draa, highlighting the necessity of additional field studies in this area. Another observation to be remarked is that *F. lybica* and *F. margarita* can be found in syntopy in Morocco, as confirmed by our records from Smara (Fig. 1). Finally, the negative effect that water cisterns might pose to these two species should be highlighted. Two out of three *F. margarita* and 27 out of 43 *F. lybica* individuals were found dead in these structures either from dehydration or starvation if cisterns are dry, or from drowning if cisterns are filled. This suggests that some of these might act as death traps, as has been shown for many small vertebrates of this region such as reptiles (García-Cardenete *et al.* 2014) and small mammals (authors unpublished data). In fact, such small vertebrates might act as baits, attracting the feline predators towards these traps. The type of construction and their conditions greatly influences their lethality however and partially collapsed or sand filled cisterns may also serve as refuges. For example, a record of a female *Felis lybica* and three cubs suggests that water cisterns can also serve as

breeding dens for this species. It is important to stress that records we report here are opportunistic and prone to bias, but they highlight the need for more detailed and quantitative field studies to properly assess the fine-scale distribution of these elusive species and the impact of water cisterns.
